WHAT COULD BE CHANGED?

The main question that stuck with me from the exhibition, where Mandar Sir had asked us, “Imagine, in the future, you got another chance to make this project, what would you change that you wish you had?”

The thing that instantly comes to our mind is the placement of the arrow on the crossbow. Currently, we place it on the centre MDF piece. But the problem that arises, which is very small, is that when we move the crossbow to align it with our target holes, the abrupt movement displaces the straight position of the arrow due to the lack of anything that would hold it straight. So, the first thing we would do is add two pin-like or wall-like structures that hold the arrow in place.

We would invest more time in cleanly segregating all components and their wired connections so it is easier to fix errors and maintain uniformity every time we run the code. The lack of this act impacted the functioning of our DC motor, and also the servo motors in the beginning. And I feel a better system could also remove chances of lag or delay, which might be caused by loose connections.
